

A detailed 3D illustration of several cancer cells. The cells are depicted with a textured, orange-brown surface and numerous thin, hair-like projections (microvilli) extending from them. Some cells are shown in the process of dividing or interacting with smaller, blue-green spherical particles. The background is a deep blue with a wavy, undulating texture.

Cancer Introduction

Cancer is a disease caused by the loss of normal regulation and excessive proliferation of cells in the body. Cells that proliferate excessively are called cancer cells. Cancer cells may invade surrounding tissues (invasion) and even metastasize to other parts of the body through the circulatory system and/or lymphatic system (cancer metastasis).

Normal cell proliferation is tightly regulated with a balance between the activities of proto-oncogenes and tumor suppressors. For example, DNA damage and repair mechanisms exist in order to decrease the likelihood of genetic mutation and cell transformation. Accumulating disruptions in these homeostatic control mechanisms can lead to unregulated proliferation and cancer. Whereas normal cells differentiate into very different cell types when they mature, cancer cells are less differentiated and aggressive and often gain the ability to avoid programmed cell death (apoptosis). Out-of-control tumor cells can also evade the immune system by hiding themselves and influence the tumor microenvironment, promoting angiogenesis and providing oxygen and nutrients to the tumor.

Elabscience® provides customers with high-quality ELISA Kits to study multiple aspects of the cancer area, including cancer immunology, tumor suppressors, growth factors, apoptosis, cancer biomarkers and more.

About Elabscience®

Elabscience® is a high-tech biological company specializing in the development, production and sales of immunoassay reagents. The main products are **ELISA Kits, CLIA Kits, FCM Antibodies, Cell Function Assays, Metabolism Assay Kits, Antibodies, Proteins, Labeling Kits, Immunology Related Reagents**, etc.

Customer Distribution

The customers are distributed in more than **150 countries** on **5 continents**, basically covering all famous universities and research institutions in the world.

Why Choose Elabscience® ELISA Kits?

Strict Quality Control

- 8 processes for strict quality control
- Superior performance guarantees

Recommended by CiteAb

- In 2019, Elabscience® was highly commended as "ELISA KIT SUPPLIER TO WATCH IN 2019" by CiteAb

Supported by 10000+ SCI Literatures

- Elabscience® products have been cited in more than **10,000** SCI papers, and published in *Nature Medicine*, *Nature*, *Cell*, *Immunity*, *Molecular Cancer* and other internationally renowned journals.

ELISA Kits Features

- ♥ High precision: Both inter and intra CV are <10%
- ♥ High sensitivity: Pg level
- ♥ Good specificity: Cross-reactivity <10%
- ♥ High precision over thousands of items: Covering various targets and species
- ♥ Flexible choices on size: 48T/96T/96T*5/96T*10
- ♥ One-step method available

01 Cancer Immunology

Biological cells have a certain rate of variation in the normal process of division and proliferation, but the mutant cells are not necessarily malignant cells, and the tumor formed by malignant cells is the result of cell division and differentiation disorders. These malignant cells have many differences from the original normal cells (such as accompanied by new antigens), and thus can cause the body's immune response.

Cancer cells employ several immunosuppressive mechanisms to prevent the protective function of the immune system. For example, they can downregulate the expression of tumor antigens on their surface to evade recognition. To suppress immune function, these cells secrete paracrine mediators and suppressive cytokines which operate to inhibit the penetration of T cells into the tumor, inactivate effector T cells, and activate suppressor T cells.

02 Tumor Microenvironment

The tumor microenvironment time (TME) refers to the interactions between heterogeneous cell types and the extracellular matrix (ECM) within a cancerous lesion, and mediates the key processes of angiogenesis, ECM remodeling and immunosurveillance inhibition. TME plays a key role in regulating the immune response of cancer patients. Tumor cells and their microenvironment typically produce a large number of immunomodulatory molecules that negatively (suppressor) or positively (activator) affect the function of immune cells. Thus, TME is able to shift the immune response from a tumor-destructive mode to a tumor-promoting mode based on the composition of the TME. Among them, immune cells, soluble mediators (cytokines, chemokines, angiogenic factors, lymphangiogenic factors and growth factors) and cell receptors in TME play key roles in immune response.

Fig.3 The p53 Tumor Suppressor Protein Binds to DNA

03 Tumor Suppressors

Tumor suppressor genes exist in normal cells and regulate cell growth and differentiation together with proto-oncogenes. Tumor suppressor genes play a very important negative regulatory role in the control of cell growth, proliferation and differentiation. They interact with proto-oncogenes to maintain the relative stability of positive and negative regulatory signals. When these genes are mutated, deleted or inactivated, they can cause malignant transformation of cells and lead to the occurrence of tumors. So far, scientists have isolated and identified about 100 tumor suppressor genes from cells, the most common genes such as Rb (retinoblastoma gene), p53, APC, NM23 and so on. Normal people have complete Rb gene, the partial deletion of Rb gene, can cause a variety of cancers such as retinoblastoma and colon cancer.

Fig.4 Vascular Endothelial Growth Factor Receptors are Activated by VEGF

04 Growth Factors

Growth factors are a class of peptides that regulate cell growth and other cell functions by binding to specific and highly affinity cell membrane receptors, and promote growth and development by directing cell maturation and differentiation and by mediating maintenance and repair of tissues. They have an array of putative functions during development including regulating tissue morphogenesis, angiogenesis, cell differentiation, and neurite outgrowth. They also play important roles in the maintenance of tissue homeostasis and wound healing in the adult.

Growth factors are also key players in tumor progression, and are involved in clonal expansion, tissue invasion and angiogenesis. Important growth factors include vascular endothelial growth factor (VEGF), epidermal growth factor (EGF), fibroblast growth factor (FGF), platelet-like growth factor (PDGF), insulin-like growth factor (IGF), and nerve growth factor (NGF).

05 cell cycle

Cell cycle refers to the whole process that a cell goes through from the completion of one division to the end of the next division, which is divided into two stages: interphase and mitotic phase. During interphase, the cell grows, accumulating nutrients needed for mitosis, and replicates its DNA and some of its organelles. During the mitotic phase, the replicated chromosomes, organelles, and cytoplasm separate into two new daughter cells. To ensure the proper replication of cellular components and division, there are control mechanisms known as cell cycle checkpoints after each of the key steps of the cycle that determine if the cell can progress to the next phase.

The cell-division cycle is a vital process by which a single-celled fertilized egg develops into a mature organism, as well as the process by which hair, skin, blood cells, and some internal organs are renewed. Disruption of the normal cell cycle underpins the characteristic uncontrolled cell division in cancer. Deregulation of the cell cycle is a consequence of aberrant activity of cell cycle-associated kinases or phosphatases.

Fig.6 Apoptosis Stages Schematic

06 Apoptosis

Apoptosis is a form of programmed cell death that occurs in multicellular organisms and plays a key role in development and immunity as well as in cancer and neurodegenerative diseases. Biochemical events lead to characteristic cell changes (morphology) and death. These changes include blebbing, cell shrinkage, nuclear fragmentation, chromatin condensation, chromosomal DNA fragmentation, and global mRNA decay, and ultimately the formation of apoptotic bodies that can be efficiently cleared by phagocytes.

Apoptosis can be initiated via several mechanisms including trophic factor withdrawal, ligation of pro-apoptotic transmembrane receptors, or the activities of cytotoxic immune cells. Excessive apoptosis causes atrophy, whereas an insufficient amount results in uncontrolled cell proliferation, such as cancer. Some factors like Fas receptors and caspases promote apoptosis, while some members of the Bcl-2 family of proteins inhibit apoptosis.

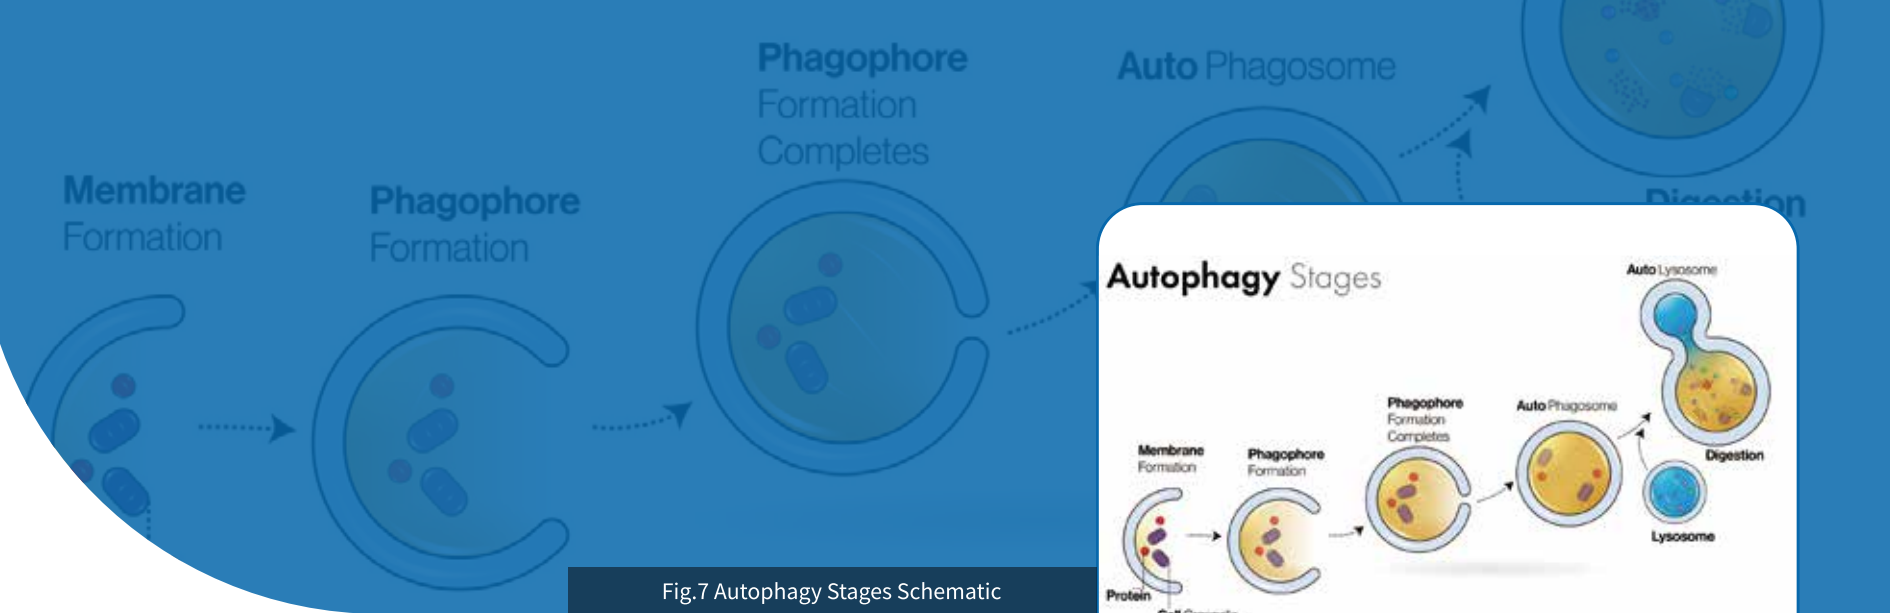

Fig.7 Autophagy Stages Schematic

07 Autophagy

Autophagy is the biological process in which endogenous proteins and damaged organelles are degraded by cellular self-digestion. It is the orderly degradation and recycling of cellular components. There are three main forms of autophagy: microautophagy, macroautophagy and chaperone-mediated autophagy (CMA). Some damaged proteins or organelles during autophagy are wrapped by bilayer membrane structure autophagy vesicles and sent to lysosomes (animals) or vacuoles (yeast and plants) for degradation and recycling.

In disease, autophagy has been seen as an adaptive response to stress, promoting survival of the cell; but in other cases it appears to promote cell death and morbidity. In the extreme case of starvation, the breakdown of cellular components promotes cellular survival by maintaining cellular energy levels. Defects in autophagy have been linked to various human diseases, including neurodegeneration and cancer, and interest in modulating autophagy as a potential treatment for these diseases has grown rapidly.

Fig.8 Cancer Biomarkers Schematic

08 Cancer Biomarkers

Cancer Biomarkers are endogenous proteins or metabolites that are produced directly by tumor cells or induced by non-tumor cells through tumor cells, and whose amounts and modifications are indicative of tumor state, progression characteristics, and response to therapies. They are present in the tissues, body fluids and excreta of tumor patients and contain a variety of molecules: a, The metabolites of tumor cells, such as glycolysis products, tissue polypeptide antigens, nucleic acid decomposition products. b, Cell gene products with disordered differentiation, such as ectopic ACTH fragments, alpha-fetoprotein, carcinoembryonic antigen, fetal isoenzyme. c, Some cytoskeletal protein components, such as cytokeratin fragment antigen 21-1 (Cyfra21-1) and polyamines, are the main substances released into the blood circulation by necrosis and disintegration of tumor cells. d, Cell reactivity products of tumor host cells, such as VCA-IgA and EA-IgA.

SAA(Serum Amyloid A)	E-EL-H2183	Human	1.25-80ng/mL	0.75ng/mL
	E-EL-M3045	Mouse	125-8000pg/mL	75.00pg/mL
	E-EL-R3026	Rat	1.56-100pg/mL	0.94pg/mL
SPARCL1(SPARC Like Protein 1)	E-EL-H1273	Human	0.31-20ng/mL	0.19ng/mL
TLR-2(Toll-like Receptor 2)	E-EL-H0951	Human	0.31-20ng/mL	0.19ng/mL
	E-EL-R0907	Rat	0.31-20ng/mL	0.19ng/mL
TNC(Tenascin C)	E-EL-M3047	Mouse	31.25-2000pg/mL	18.75pg/mL
TP53(Tumor Protein p53)	E-EL-H0910	Human	78.13-5000pg/mL	46.88pg/mL
tPA(Tissue-type Plasminogen Activator)	E-EL-H2106	Human	0.63-40ng/mL	0.38ng/mL
	E-EL-M0917	Mouse	39.06-2500pg/mL	23.44pg/mL

Fig.9 Cancer Cell Targets

09 Cancer Drug Targets

In recent years, with the rapid development of tumor biology and related disciplines, people gradually realize that the essence of cell cancerosis is infinite cell proliferation caused by the disorder of cell signal transduction pathway, which is followed by a major change in the concept of anticancer drug research and development. The focus of research and development is shifting from traditional cytotoxic drugs to a new generation of anti-cancer drugs specific to targets of abnormal signaling systems within cancer cells. Different from traditional cytotoxic drugs, such as poor selectivity, strong side effects and easy to produce drug resistance, target-specific anti-cancer drugs target at the difference between normal cells and tumor cells, achieving high selectivity and low toxicity therapeutic effect. These include targeted tyrosine kinases, angiogenesis, tumor cell cycle related factors, histone deacetylase inhibitors, microenvironments, tumor stem cells, and tumor metabolic abnormalities.

Targets	Cat.No.	Literature Information	Research Area	Impact Factor
Mouse CRP	E-EL-M0053	Li X X, Wu T, Zhang Z F, et al. Tumor Microenvironment Activated Nanoreactors for Chemiluminescence Imaging-Guided Simultaneous Elimination of Breast Tumors and Tumor-Resident Intracellular Pathogens[J]. Chemical Engineering Journal, 2023.	Cancer Cell Biology	16.744
Mouse HMGB-1	E-EL-M0676	Hu M, Zhang J, Kong L, et al. Immunogenic Hybrid Nanovesicles of Liposomes and Tumor-Derived Nanovesicles for Cancer Immunotherapy[J]. ACS Nano, 2021, 15(2): 3123-3138.	Cancer Immunology	15.881
Mouse GM-CSF Mouse IL-1 α Mouse MCP-1 Mouse MIP-1 α Mouse MIP-3 α Mouse TNF- α	E-EL-M0032 E-EL-M3059 E-EL-M3001 E-EL-M3059 E-EL-M0013 E-EL-M3063	Zhou Y H, Ye T, Ye C Z, et al. Secretions from Hypochlorous Acid-treated Tumor Cells Delivered in a Melittin Hydrogel Potentiate Cancer Immunotherapy[J]. Bioactive Materials, 2021, 9: 541-553.	Cancer Immunology	14.593
